# Introduction

- Images have become an essential part of our daily lives and are used for both practical and aesthetic purposes.
- images are used in a variety of applications and industries today.

Starting from self driving cars, education, medicine, and surveillance.

- Due to bad weather or light effects image gets noisy and hazy.

This may include haziness and dim light images.

- ➡ In order to reduce the haziness and improve the brightness of the dim light image I have proposed an architecture.

# Image in different environments

Balanced image

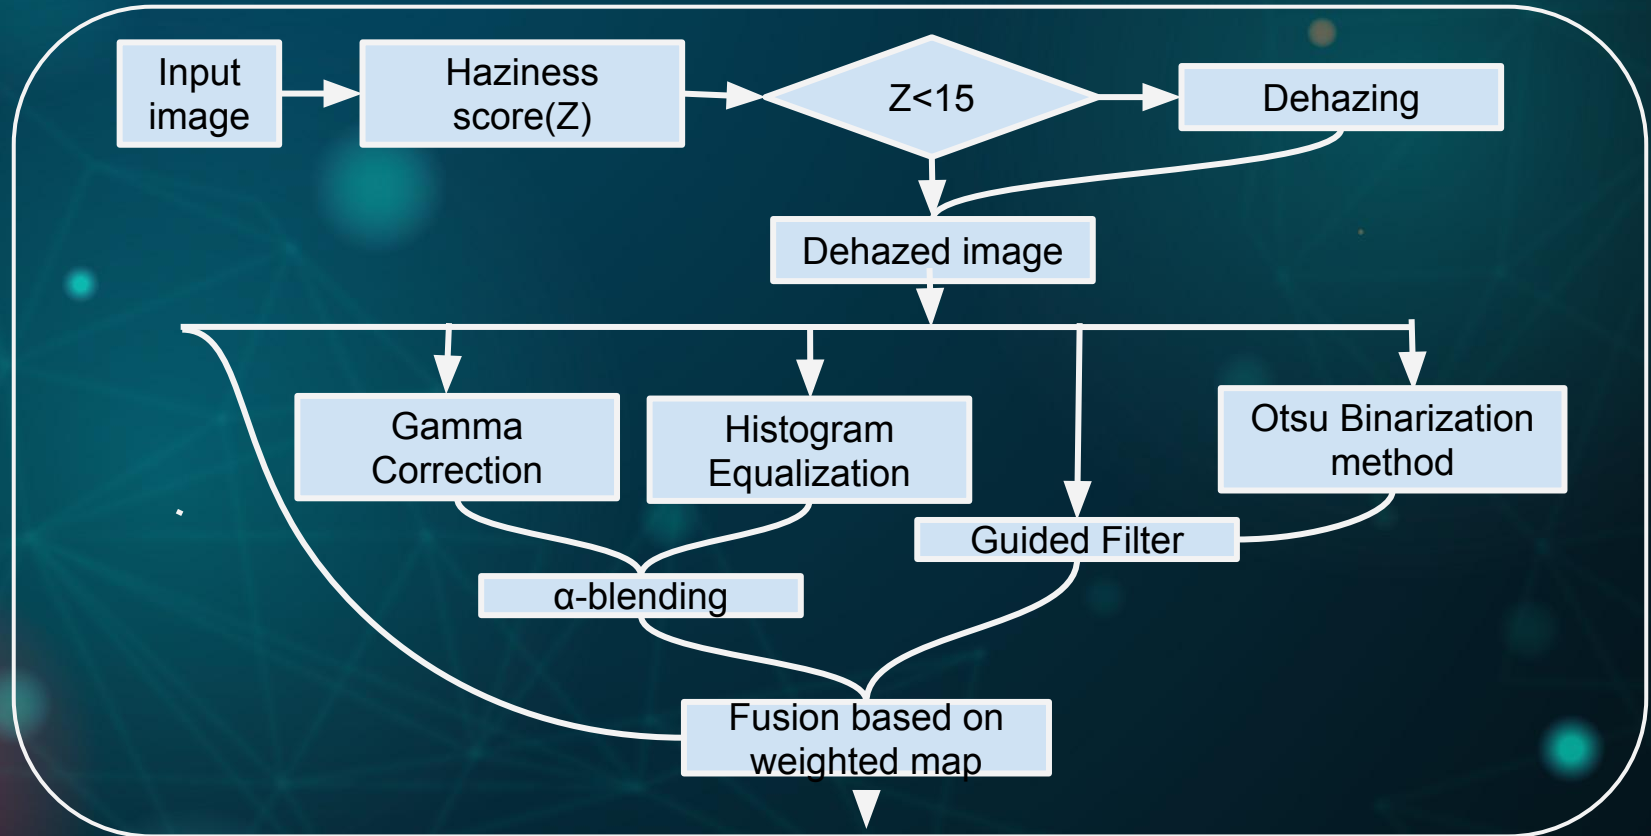

Hazy Image

Dim-light image

# Proposed Architecture

# Dehazing

- caused by the presence of unwanted atmospheric particles or haze that scatter light and reduce the clarity of the image.
- **Solution: Dehazing based on colorline**
  - Main Idea: the color line of an image changes as a result of atmospheric haze and gets shifted.
  - The haze-free color line is calculated by fitting a smooth curve through the data points on the color line.
  - The difference between the original color line and the haze-free color line is used to estimate the amount of haze in the image.
  - Finally, the haze is removed by subtracting the haze-free color line from the original color line and adding the result back to the image.

# Dehazing

## Haziness score calculation using Laplacian dehazing

- Takes second derivative of the image on some higher dimensional plane and finds area of rapid changes in images given there is no noise.
- If the image is uniform, the result will be zero.
- Wherever a change occurs, the resultant will have positive value.
- With taking a fixed threshold we can determine the haziness of a image.

# Gamma Correction

- Non-linear adjustment to individual pixel values of given image.
- Increase overall brightness of the image.
- Lower gamma value(eg 0.5) makes image brighter.
- Higher gamma value(eg 2.5) reduce image contrast.

$$O_{ij}^{gamma} = 255. (I_{ij}^{input} / 255)^{1/\gamma}$$

# Gamma Correction

For Gamma = 0.5

# Histogram Equalization

- Improves the contrast of the image
- spread the pixel intensity values of an image over a wider range, such that the distribution of pixel intensities becomes more uniform.
- This results in more evenly distributed image pixels.

# Histogram Equalization

# Alpha Blending

- combine two images or layers with transparency, resulting a single image.
- Alpha ranges between 0(full transparent) to 1(full opaque)
- The alpha value determines how much of the foreground color should be mixed with the background color

$$C_{out} = (1 - \alpha) * C_{bg} + \alpha * C_{fg}$$

$C_{out}$  is the output color of a pixel,  
 $C_{bg}$  is the background color,  
 $C_{fg}$  is the foreground color, and  
alpha is the alpha value of the foreground color.

# Guided Image Filtering

- efficient method for image smoothing and enhancement that preserves edges
- non-linear filtering method that uses a guidance image to control the filtering process.
- The guidance image is typically a low-resolution version of the original image that contains information about the structure and edges of the image.
